# Data Mining: Data

Tom Heskes

# **Class Project**

- Hands-on experience with data mining
- Two options:
  - "Problem"
  - "Algorithm"
- Two phases:
  - Proposal: soft deadline (see Brightspace)
  - Final report: hard deadline (see Brightspace)

#### "Problem"

- Find a data set and corresponding problem
- Find a work bench of data mining / machine learning algorithms
- Apply at least two different algorithms to your problem
- Write a report

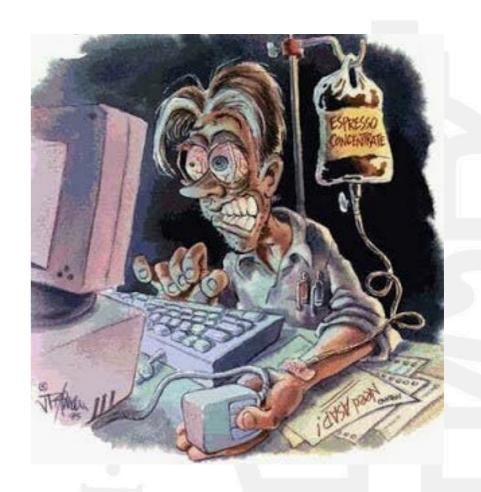

"You can't keep adjusting the data to prove that you would be the best Valentine's date for Scarlett Johansson."

# "Algorithm"

- Choose one or at most two challenging data mining algorithms that you'd like to implement yourself
- Implement them and apply them to a suitable data set
- Write a report

#### **Practicalities**

- Groups of 2 or by yourself
- Data: see Brightspace
- Software: see Brightspace
- If you're stuck: ask!
- Do not underestimate!!!!!!

#### What is Data?

- Collection of data objects and their attributes
- An attribute is a property or characteristic of an object
  - Examples: eye color of a person, temperature, etc.
  - Attribute is also known as variable, field, characteristic, or feature
- A collection of attributes describe an object
  - Object is also known as record, point, case, sample, entity, or instance

#### **Attributes**

Tid	Refund	Marital Status	Taxable Income	Cheat	
1	Yes	Single	125K	No	
2	No	Married	100K	No	
3	No	Single	70K	No	
4	Yes	Married	120K	No	
5	No	Divorced	95K	Yes	
6	No	Married	60K	No	
7	Yes	Divorced	220K	No	
8	No	Single	85K	Yes	
9	No	Married	75K	No	
10	No	Single	90K	Yes	

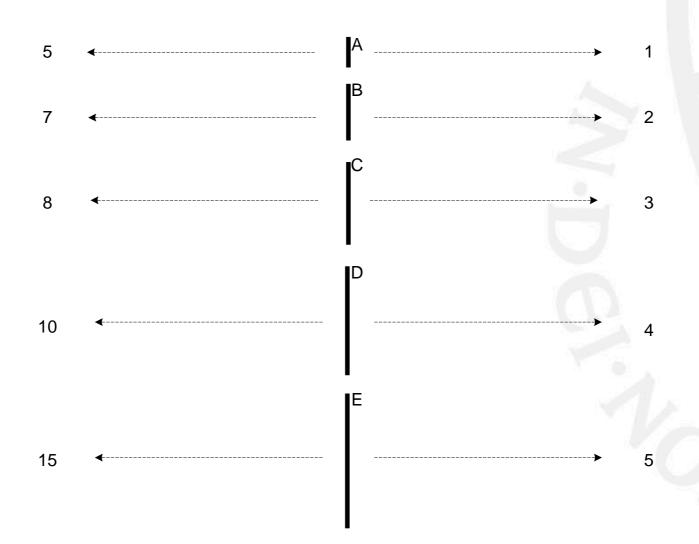

#### **Attribute Values**

- Attribute values are numbers or symbols assigned to an attribute
- Distinction between attributes and attribute values
  - Same attribute can be mapped to different attribute values
  - Example: height can be measured in feet or meters
  - Different attributes can be mapped to the same set of values
  - Example: Attribute values for ID and age are integers

# **Measurement of Length**

- The way you measure an attribute is somewhat arbitrary.
- Rely on common sense.

# **Types of Attributes**

- There are different types of attributes
  - Nominal
    - Examples: ID numbers, eye color, zip codes
  - Ordinal
    - Examples: rankings (e.g., taste of potato chips on a scale from 1-10), grades, height in {tall, medium, short}
  - Interval
    - Examples: calendar dates, temperatures in Celsius or Fahrenheit.
  - Ratio
    - Examples: temperature in Kelvin, length, time, counts

# **Properties of Attribute Values**

Mathematical properties / operations:

Distinctness: = 5Order: < 2</li>Addition: + 5

- Multiplication: \*/

- The type of an attribute depends on which of these apply:
  - Nominal attribute: distinctness
  - Ordinal attribute: distinctness & order
  - Interval attribute: distinctness, order & addition
  - Ratio attribute: all 4 properties

#### **Discrete and Continuous Attributes**

#### Discrete Attribute

- Has only a finite or countably infinite set of values
- Examples: zip codes, counts, or the set of words in a collection of documents
- Often represented as integer variables.
- Note: binary attributes are a special case of discrete attributes

#### Continuous Attribute

- Has real numbers as attribute values
- Examples: temperature, height, or weight.
- Practically, real values can only be measured and represented using a finite number of digits.
- Continuous attributes are typically represented as floating-point variables.

# **Examples**

For each of the following attributes, say whether it's binary, discrete, or continuous and whether it's nominal, ordinal, interval, or ratio.

- Age in years
- Time in terms of AM or PM
- Brightness as measured by a light meter
- Brightness as measured by people's judgments
- Bronze, silver, and gold medals as awarded at the Olympics
- Height above sea level
- Number of patients in a hospital
- ISBN numbers for books
- Military rank
- Distance from the center of campus
- Temperature in degrees Kelvin
- Temperature in degrees Celsius
- Coat check number

# Types of data sets

- Record
  - Data matrix
  - Document data
  - Transaction data
- Graph
  - World Wide Web
  - Molecular structures
- Ordered
  - Spatial data
  - Temporal data
  - Sequential data
  - Genetic sequence data

#### **Record Data**

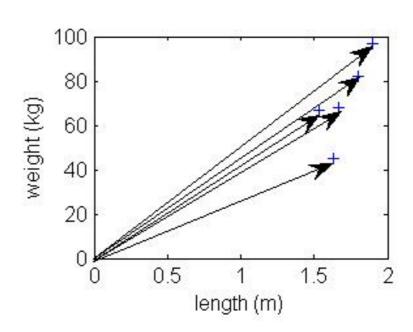

Data that consists of a collection of records, each of which consists of a fixed set of attributes

Tid	Refund	Marital Status	Taxable Income	Cheat	
1	Yes	Single	125K	No	
2	No	Married	100K	No	
3	No	Single	70K	No	
4	Yes	Married	120K	No	
5	No	Divorced	95K	Yes	
6	No	Married	60K	No	
7	Yes	Divorced	220K	No	
8	No	Single	85K	Yes	
9	No	Married	75K	No	
10	No	Single	90K	Yes	

#### **Data Matrix**

- If data objects have the same fixed set of numeric attributes, then the data objects can be thought of as points in a multi-dimensional space, where each dimension represents a distinct attribute
- Such data set can be represented by an m by n matrix, where there are m rows, one for each object, and n columns, one for each attribute

Tid	Length	Weight
1	1.80	82
2	1.53	67
3	1.67	68
4	1.90	97
5	1.63	45

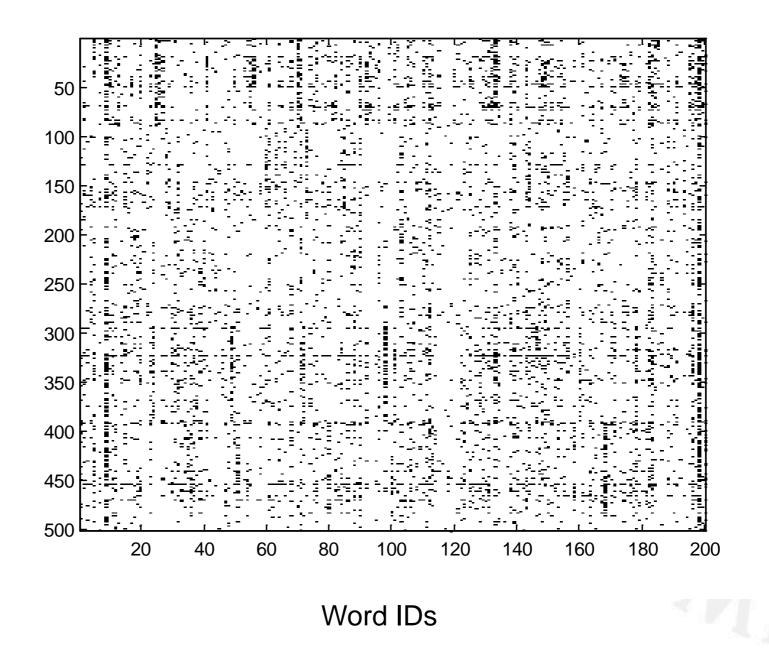

#### **Document Data**

- Each document becomes a 'term' vector
  - each term is a component (attribute) of the vector
  - the value of each component is the number of times the corresponding term occurs in the document

Document	team	coach	play	ball	score	game	win	lost	timeout	season
1	3	0	5	0	2	6	0	2	0	2
2	0	7	0	2	1	0	0	3	0	0
3	0	1	0	0	1	2	2	0	3	0
4	1	4	0	2	3	0	1	6	2	1
5	2	3	3	1	6	1	3	0	0	4

# **Sparse Document Matrix**

Text documents

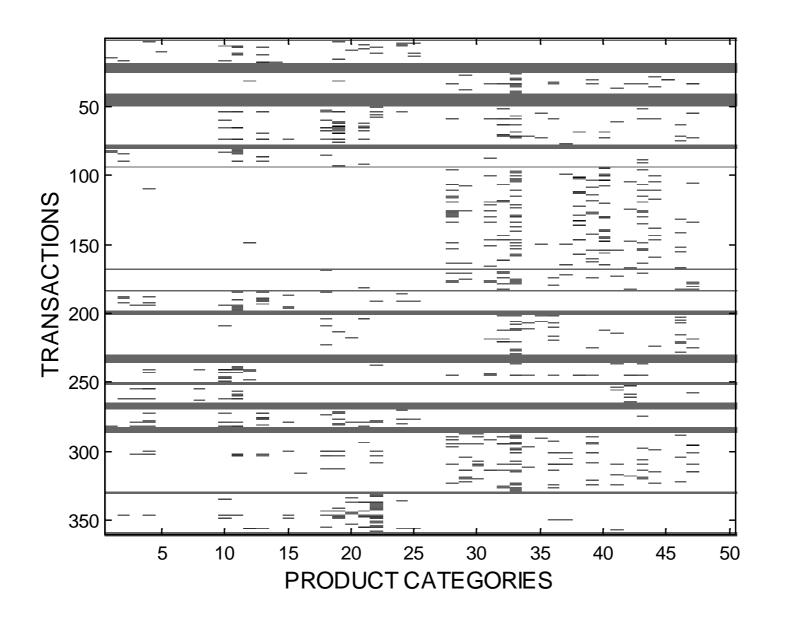

#### **Transaction Data**

- A special type of record data, where
  - each record (transaction) involves a set of items.
  - For example, consider a grocery store. The set of products purchased by a customer during one shopping trip constitutes a transaction, while the individual products that were purchased are the items.

TID	Items
1	Bread, Coke, Milk
2	Beer, Bread
3	Beer, Coke, Diaper, Milk
4	Beer, Bread, Diaper, Milk
5	Coke, Diaper, Milk

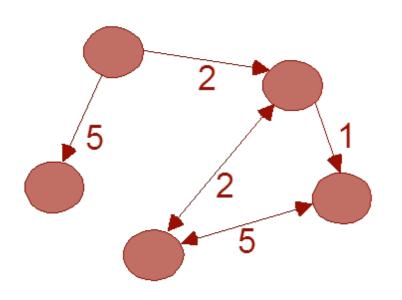

### **Market Basket Data**

# **Graph Data**

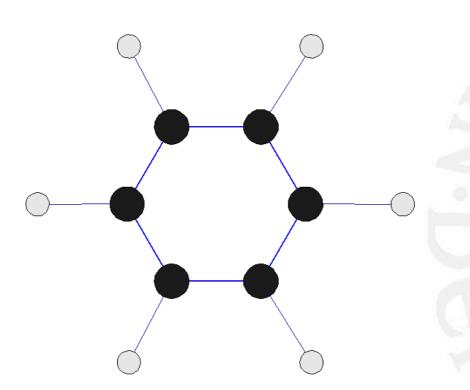

Examples: Generic graph and HTML Links

<a href="papers/papers.html#bbbb">
Data Mining </a>
<a href="papers/papers.html#aaaa">
Graph Partitioning </a>
<a href="papers/papers.html#aaaa">
Parallel Solution of Sparse Linear System of Equations </a>
<a href="papers/papers.html#ffff">
N-Body Computation and Dense Linear System Solvers</a>

### **Chemical Data**

Benzene molecule: C<sub>6</sub>H<sub>6</sub>

### Sequence (Web) Data

### **Email Network**

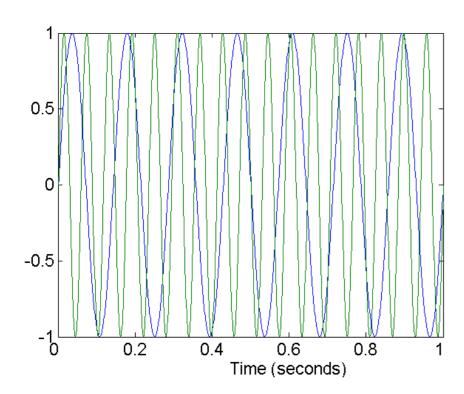

# **Data Quality**

- Data is of high quality if they
  - Are fit for their intended use
  - Correctly represent the phenomena they correspond to
- Examples of data quality problems:
  - noise and outliers
  - missing values
  - duplicate data

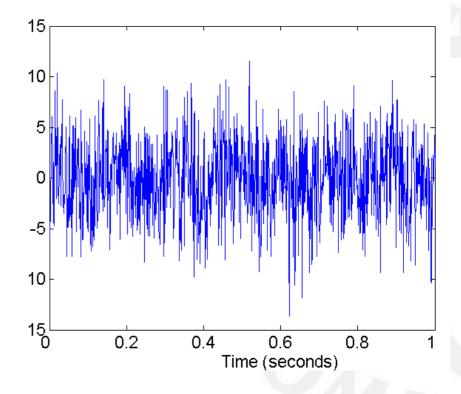

#### **Noise**

- Noise refers to modification of original values
  - Examples: distortion of a person's voice when talking on a poor phone and "snow" on television screen

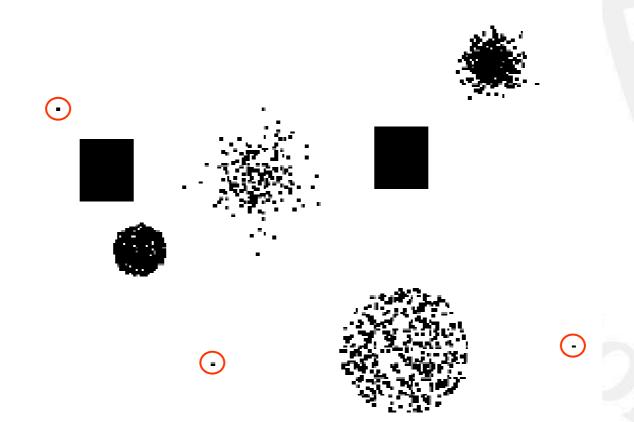

Two sine waves

Two sine waves + noise

#### **Outliers**

Outliers are data objects with characteristics that are considerably different than most of the other data objects in the data set

# Missing Values

- Reasons for missing values
  - Information is not collected
     (e.g., people decline to give their age and weight)
  - Attributes may not be applicable to all cases (e.g., annual income is not applicable to children)
- Handling missing values
  - Eliminate data objects
  - Estimate missing values
  - Ignore the missing value during analysis
  - Replace with all possible values (weighted by their probabilities)

# **Duplicate Data**

- Data set may include data objects that are duplicates, or almost duplicates of one another
  - Major issue when merging data from heterogeneous sources
- Example: same person with multiple email addresses
- Data cleaning

# **Data Preprocessing**

- Aggregation
- Sampling
- Dimensionality reduction
- Feature subset selection
- Feature creation
- Discretization
- Attribute transformation

### **Aggregation**

Combining two or more attributes (or objects) into a single attribute (or object)

#### Purpose

- Data reduction: reduce the number of attributes or objects
- Change of scale: cities aggregated into regions, states, countries, etc
- More "stable" data: aggregated data tends to have less variability

# **Sampling**

- Sampling is the main technique employed for data selection.
  - Used for both the preliminary investigation of the data and the final analysis.
- Statisticians sample because obtaining the entire set of data of interest is too expensive or time consuming.
- Sampling is used in data mining because processing the entire set of data of interest is too expensive or time consuming.
- Key principle for effective sampling:
  - Using a sample will work almost as well as using the entire data sets, if the sample is representative
  - A sample is representative if it has approximately the same property (of interest) as the original set of data

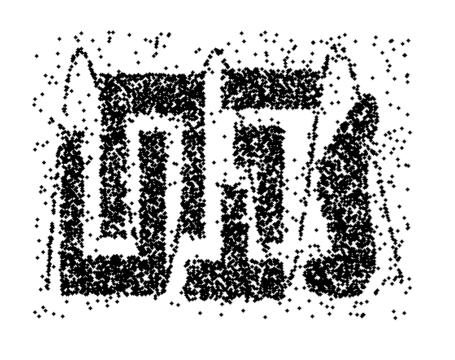

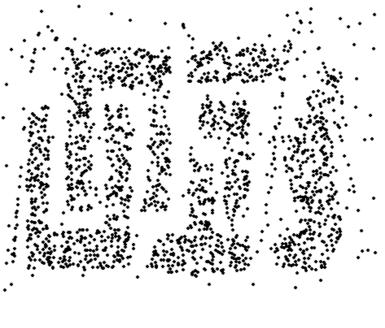

# **Types of Sampling**

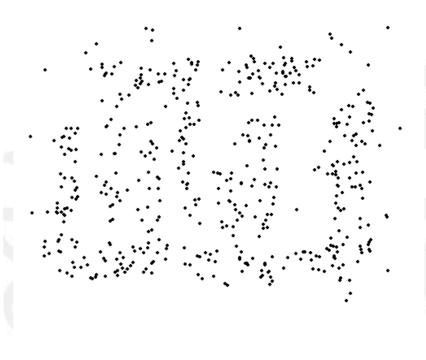

- Simple Random Sampling
  - There is an equal probability of selecting any particular item
- Sampling without replacement
  - As each item is selected, it is removed from the population
- Sampling with replacement
  - Objects are not removed from the population as they are selected for the sample: the same object can be picked up more than once
- Stratified sampling
  - Split the data into several partitions; then draw random samples from each partition

# **Sample Size**

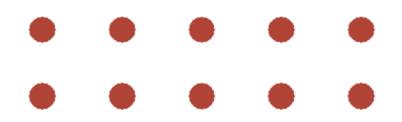

8000 points

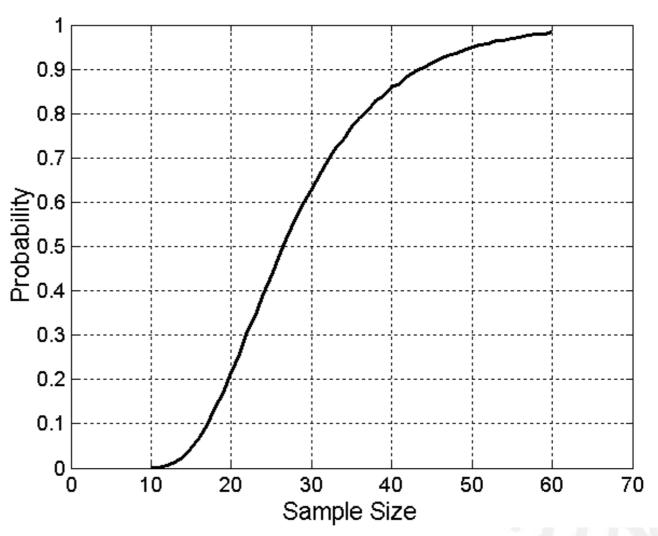

2000 Points

500 Points

### **Sample Size**

What sample size is necessary to get at least one object from each of 10 groups?

## **Python Code Sample Size**

import numpy as np

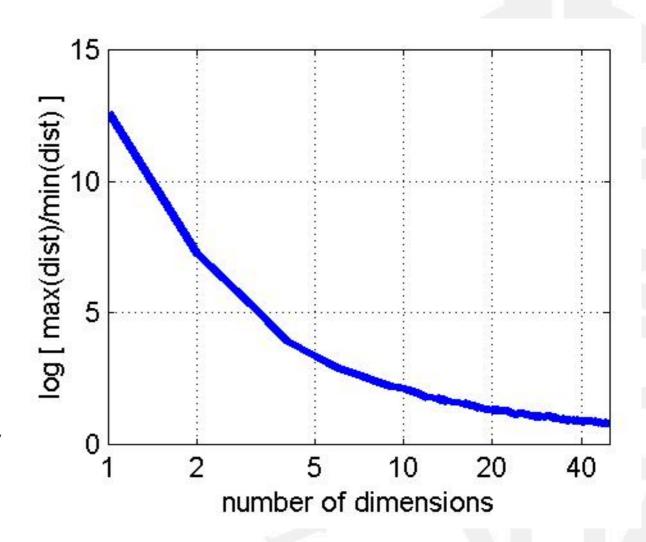

```
nclusters = 10
npoints = 40
nsamples = 10000

pvals = np.ones((nclusters))/nclusters
x = np.random.multinomial(npoints, pvals, (nsamples))

teller = all(x, axis=1)
ppp = sum(teller)/float(nsamples)
```

### **Curse of Dimensionality**

- When dimensionality increases, data becomes increasingly sparse in the space that it occupies
- Definitions of density and distance between points, which is critical for clustering and outlier detection, become less meaningful

- Randomly generate 500 points
- Compute (log) ratio of max and min distance between any pair of points

### **Python Code Curse of Dimensionality**

```
import numpy as np
import scipy.spatial.distance
import matplotlib.pyplot as plt
dimension = 40
ndatapoints = 500
x = np.random.rand(ndatapoints,dimension)
dists = scipy.spatial.distance.pdist(x,'euclidean')
plt.hist(dists)
plt.xlabel('distances')
plt.ylabel('frequency')
mindist = min(dists)
maxdist = max(dists)
```

### **Dimensionality Reduction**

#### Purpose:

- Avoid curse of dimensionality
- Reduce amount of time and memory required by data mining algorithms
- Allow data to be more easily visualized
- May help to eliminate irrelevant features or reduce noise

#### Techniques

- Principal Component Analysis
- Singular Value Decomposition
- Others: supervised and non-linear techniques

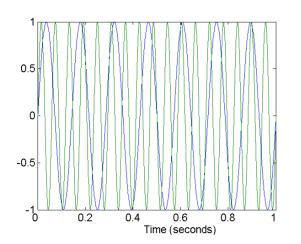

### **Feature Subset Selection**

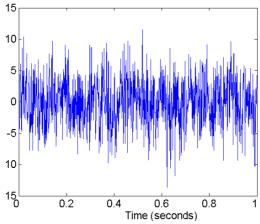

### Techniques:

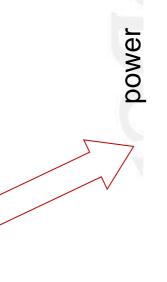

- Brute-force approach: Try all possible feature subsets as input to data mining algorithm
- Embedded approaches: Feature selection occurs naturally as part of the data mining algorithm
- Filter approaches: Features are selected before data mining algorithm is run
- Wrapper approaches: Use the data mining algorithm as a black box to find best subset of attributes

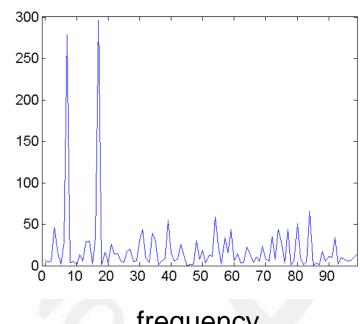

### **Feature Creation**

- Create new attributes that can capture the important information in a data set much more efficiently than the original attributes
- Combining features
  - For example, BMI instead of length and weight separately
  - Particularly relevant for restricted (e.g., linear) models
- Mapping data to a new space
  - For example, Fourier transform

frequency

### **Attribute Transformation**

- A function that maps the entire set of values of a given attribute to a new set of values such that each old value can be identified with one of the new values
  - Simple functions:  $x^k$ ,  $\log x$ ,  $e^x$ , |x|
  - Standardization and normalization
- For many data mining algorithms, continuous features are preferentially more or less normally distributed
- Log transformation often useful for positive features such as income, height, etc.
